Abstract

We share a French-English parallel corpus of Foursquare restaurant reviews, and define a new task to encourage research on Neural Machine Translation robustness and domain adaptation, in a real-world scenario where better-quality MT would be greatly beneficial. We discuss the challenges of such user-generated content, and train good baseline models that build upon the latest techniques for MT robustness. We also perform an extensive evaluation (automatic and human) that shows significant improvements over existing online systems. Finally, we propose task-specific metrics based on sentiment analysis or translation accuracy of domain-specific polysemous words.

1 Introduction

Very detailed information about social venues such as restaurants is available from user-generated reviews in applications like Google Maps, TripAdvisor or Foursquare.¹ Most of these reviews are written in the local language and are not directly exploitable by foreign visitors: an analysis of the Foursquare database shows that, in Paris, only 49% of the restaurants have at least one review in English. It can be much worse for other cities and languages (e.g., only 1% of Seoul restaurants for a French-only speaker).

Machine Translation of such user-generated content can improve the situation and make the data available for direct display or for downstream NLP tasks (e.g., cross-lingual information retrieval, sentiment analysis, spam or fake review detection), provided its quality is sufficient.

We asked professionals to translate 11.5k French Foursquare reviews (18k sentences) to English. We believe that this resource² will be valuable to the community for training and evaluating

¹<https://foursquare.com/>

²<https://europe.naverlabs.com/research/natural-language-processing/machine-translation-of-restaurant-reviews/>

MT systems addressing challenges posed by user-generated content, which we discuss in detail in this paper.

We conduct extensive experiments and combine techniques that seek to solve these challenges (e.g., factored case, noise generation, domain adaptation with tags) on top of a strong Transformer baseline. In addition to BLEU evaluation and human evaluation, we use targeted metrics that measure how well polysemous words are translated, or how well sentiments expressed in the original review can still be recovered from its translation.

2 Related work

Translating restaurant reviews written by casual customers presents several difficulties for NMT, in particular robustness to non-standard language and adaptation to a specific style or domain (see Section 3.2 for details).

Concerning robustness to noisy user generated content, [Michel and Neubig \(2018\)](#) stress differences with traditional domain adaptation problems, and propose a typology of errors, many of which we also detected in the Foursquare data. They also released a dataset (MTNT), whose sources were selected from a social media (Reddit) on the basis of being especially noisy (see Appendix for a comparison with Foursquare). These sources were then translated by humans to produce a parallel corpus that can be used to engineer more robust NMT systems and to evaluate them. This corpus was the basis of the WMT 2019 Robustness Task ([Li et al., 2019](#)), in which [Berard et al. \(2019\)](#) ranked first. We use the same set of robustness and domain adaptation techniques, which we study more in depth and apply to our review translation task.

[Sperber et al. \(2017\)](#), [Belinkov and Bisk \(2018\)](#) and [Karpukhin et al. \(2019\)](#) propose to improve robustness by training models on data-augmented corpora, containing noisy sources obtained by random word or character deletions, insertions, sub-

stitutions or swaps. Recently, Vaibhav et al. (2019) proposed to use a similar technique along with noise generation through replacement of a clean source by one obtained by back-translation.

We employ several well-known domain adaptation techniques: back-translation of large monolingual corpora close to the domain (Sennrich et al., 2016b; Edunov et al., 2018), fine-tuning with in-domain parallel data (Luong and Manning, 2015; Freitag and Al-Onaizan, 2016; Servan et al., 2016), domain tags for knowledge transfer between domains (Kobus et al., 2017; Berard et al., 2019).

Addressing the technical issues of robustness and adaptation of an NMT system is decisive for real-world deployment, but evaluation is also critical. This aspect is stressed by Levin et al. (2017) (NMT of curated hotel descriptions), who point out that automatic metrics like BLEU tend to neglect semantic differences that have a small textual footprint, but may be seriously misleading in practice, for instance by interpreting *available parking* as if it meant *free parking*. To mitigate this, we conduct additional evaluations of our models: human evaluation, translation accuracy of polysemous words, and indirect evaluation with sentiment analysis.

3 Task description

We present a new task of restaurant review translation, which combines domain adaptation and robustness challenges.

3.1 Corpus description

We sampled 11.5k French reviews from Foursquare, mostly in the *food* category,³ split them into 18k sentences, and grouped them into train, valid and test sets (see Table 1). The French reviews contain on average 1.5 sentences and 17.9 words. Then, we hired eight professional translators to translate them to English. Two of them created the training set by post-editing (PE) the outputs of baseline NMT systems.⁴ The other six translated the valid and test sets from scratch. They were asked to translate (or post-edit) the reviews sentence-by-sentence (to avoid any alignment problem), but they could see the full context. We manually filtered the test set

³<https://developer.foursquare.com/docs/resources/categories>

⁴ConvS2S or Transformer Big trained on the “UGC” corpus described in Section 6, without domain adaptation or robustness tricks.

Split	Sentences	Reviews	Words (FR)
PE (train)	12 080	8 004	141 958
HT	2 784	1 625	29 075
valid	1 243	765	13 976
test	1 838	1 157	21 525

Table 1: Foursquare splits. Foursquare-PE is the training set. Foursquare-HT is not used in this work.

to remove translations that were not satisfactory. The full reviews and additional metadata (e.g., location and type of the restaurant) are also available as part of this resource, to encourage research on contextual machine translation.

Foursquare-HT was translated from scratch by the same translators who post-edited Foursquare-PE. While we did not use it in this work, it can be used as extra training or development data. We also release a human translation of the French-language test set (668 sentences) of the Aspect-Based Sentiment Analysis task at SemEval 2016 (Pontiki et al., 2016).

3.2 Challenges

	é qd g vu sa ...	(source)
(1)	and when I saw that ...	(reference)
	é qd g seen his ...	(online MT)
<hr/>		
	c’est trooop bon !	
(2)	it’s tooooo good!	
	it’s good trooop!	
<hr/>		
	le cadre est nul	
(3)	the setting is lousy	
	the frame is null	
<hr/>		
	le garçon a pété un cable	
(4)	the waiter went crazy	
	the boy farted a cable	
<hr/>		
	pizza nickel, tres bonnes pattes	
(5)	great pizza, very good pasta	
	nickel pizza, very good legs	

Translating restaurant reviews presents two main difficulties compared to common tasks in MT. First, the reviews are written in a casual style, close to spoken language. Some liberty is taken w.r.t. spelling, grammar, and punctuation. Slang is also very frequent. MT should be robust to these variations. Second, they generally are reactions, by clients of a restaurant, about its food quality, service or atmosphere, with specific words relating to these aspects or sentiments. These require some degree of domain adaptation. The table above illustrates these issues, with outputs from an online MT system. Examples of full reviews from Foursquare-PE along with metadata are shown in Appendix.

Examples 1 and 2 fall into the robustness cat-

egory: 1 is an extreme form of SMS-like, quasi-phonetic, language (*et quand j'ai vu ça*); 2 is a literal transcription of a long-vowel phonetic stress (*trop* → *trooop*). Example 3 falls into the domain category: in a restaurant context, *cadre* typically refers to the *setting*. Examples 4 and 5 involve both robustness and domain adaptation: *pété un cable* is a non-compositional slang expression and *garçon* is not a *boy* in this domain; *nickel* is slang for *great*, *très* is missing an accent, and *pâtes* is misspelled as *pattes*, which is another French word.

Regarding robustness, we found many of the same errors listed by Michel and Neubig (2018) as noise in social media text: SMS language (*é qd g vu sa*), typos and phonetic spelling (*pattes*), repeated letters (*trooop, merciiii*), slang (*nickel, bof, mdr*), missing or wrong accents (*tres*), emoticons (‘:-’) and emojis, missing punctuation, wrong or non-standard capitalization (lowercase proper names, capitalized words for emphasis). Regarding domain aspects, there are polysemous words with typical specific meaning (*carte* → *map, menu; cadre* → *frame, executive, setting*), idiomatic expressions (*à tomber par terre* → *to die for*), and venue-related named entities (*La Boîte à Sardines*).

4 Robustness to noise

We propose solutions for dealing with non-standard case, emoticons, emojis and other issues.

4.1 Rare character placeholder

We segment our training data into subwords with BPE (Sennrich et al., 2016c), implemented in SentencePiece (Kudo and Richardson, 2018). BPE can deal with rare or unseen words by splitting them into more frequent subwords, but cannot deal with unseen characters.⁵ While this is not a problem in most tasks, Foursquare contains many emojis, and sometimes symbols in other scripts (e.g., Arabic). Unicode now defines around 3k emojis, most of which are likely to be out-of-vocabulary.

We replace rare characters on both sides of the training corpus by a placeholder (<x>). A model trained on this data is typically able to copy the placeholder at the correct position. Then, at inference time, we replace the output tokens <x> by the rare source-side characters, in the same order. This approach is similar to that of Jean et al.

⁵Unless actually doing BPE at the *byte* level, as suggested by Radford et al. (2019).

	Uppercase	Lowercase
Input	UNE HONTE !	une honte !
Pre-proc	UN E _H ON TE _!	une _honte _!
MT output	A _H ON E Y !	A _dis gra ce !
Post-proc	A HONEY!	A disgrace!

Table 2: Capital letters break NMT. BPE segmentation and translation of capitalized or lowercase input.

(2015), who used the attention mechanism to replace UNK symbols with the aligned word in the source. Berard et al. (2019) used the same technique to deal with emojis in the WMT robustness task.

4.2 Capital letters

As shown in Table 2, capital letters are another source of confusion. *HONTE* and *honte* are considered as two different words. The former is out-of-vocabulary and is split very aggressively by BPE. This causes the MT model to hallucinate.

Lowercasing A solution is to lowercase the input, both at training and at test time. However, when doing so, some information may be lost (e.g., named entities, acronyms, emphasis) which may result in lower translation quality.

Factored translation Levin et al. (2017) do factored machine translation (Sennrich and Haddow, 2016; Garcia-Martinez et al., 2016) where a word and its case are split in two different features. For instance, *HONTE* becomes *honte + upper*.

We implement this with two embedding matrices, one for words and one for case, and represent a token as the sum of the embeddings of its factors. For the target side, we follow Garcia-Martinez et al. (2016) and have two softmax operations. We first predict the word in its lowercase form and then predict its case.⁶ The embeddings of the case and word are then summed and used as input for the next decoder step.

Inline casing Berard et al. (2019) propose another approach, *inline casing*, which does not require any change in the model. We insert the case as a regular token into the sequence right after the word. Special tokens <U>, <L> and <T> (upper, lower and title) are used for this purpose and appended to the vocabulary. Contrary to the previous solution, there is only one embedding matrix and one softmax.

⁶Like the “dependency model” of Garcia-Martinez et al. (2016), we use the current state of the decoder and the embedding of the output word to predict its case.

In practice, words are assumed to be lower-case by default and the $\langle _ \rangle$ tokens are dropped to keep the factored sequences as short as possible. “Best fries EVER” becomes “best $\langle T \rangle$ _fries _ever $\langle U \rangle$ ”. Like Berard et al. (2019), we force SentencePiece to split mixed-case words like *MacDonalds* into single-case subwords (*Mac* and *Donalds*).

Synthetic case noise Another solution that we experiment with (see Section 6) is to inject noise on the source side of the training data by changing random source words to upper (5% chance), title (10%) or lower case (20%).

4.3 Natural noise

One way to make an NMT system more robust is to train it with some of the most common errors that can be found in the in-domain data. Like Berard et al. (2019), we detect the errors that occur naturally in the in-domain data and then apply them to our training corpus, while respecting their natural distribution. We call this “natural noise generation” in opposition to what is done in (Sperber et al., 2017; Belinkov and Bisk, 2018; Vaibhav et al., 2019) or in Section 4.2, where the noise is more synthetic.

Detecting errors We compile a general-purpose French lexicon as a transducer,⁷ implemented to be traversed with extended edit distance flags, similar to Mihov and Schulz (2004). Whenever a word is not found in the lexicon (which means that it is a potential spelling mistake), we look for a French word in the lexicon within a maximum edit distance of 2, with the following set of edit operations:

- (1) deletion (e.g., *apelle* instead of *appelle*)
- (2) insertion (e.g., *apercevoir* instead of *apercevoir*)
- (3) constrained substitution on diacritics (e.g., *mangè* instead of *mangé*)
- (4) swap counted as one operation: (e.g., *mnager* instead of *manger*)
- (5) substitution (e.g., *menger* instead of *manger*)
- (6) repetitions (e.g., *Merci* with a threshold of max 10 repetitions)

We apply the transducer to the French monolingual Foursquare data (close to 1M sentences) to detect and count noisy variants of known French words. This step produces a dictionary mapping

⁷In Tamgu: <https://github.com/naver/tamgu>

the correct spelling to the list of observed errors and their respective frequencies.

In addition to automatically extracted spelling errors, we extract a set of common abbreviations from (Seddah et al., 2012) and we manually identify a list of common errors in French:

- (7) Wrong verb endings (e.g., *il a manger* instead of *il a mangé*)
- (8) Wrong spacing around punctuation symbols (e.g., *Les.plats ...* instead of *Les plats...*)
- (9) Upper case/mixed case words (e.g., *manQue de place* instead of *manque de place*)
- (10) SMS language (e.g., *bcp* instead of *beaucoup*)
- (11) Phonetic spelling (e.g., *sa* instead of *ça*)

Generating errors With this dictionary, describing the real error distribution in Foursquare text, we take our large out-of-domain training corpus, and randomly replace source-side words with one of their variants (rules 1 to 6), while respecting the frequency of this variant in the real data. We also manually define regular expressions to randomly apply rules 7 to 11 (e.g., “*e_r*” → “*é*”).

We obtain a noisy parallel corpus (which we use instead of the “clean” training data), where about 30% of all source sentences have been modified, as shown below:

Error type	Examples of sentences with injected noise
(1) (6) (9)	L’Union eUropéene espere que la réunion de suiviii entre le Président [...]
(2) (3) (10)	Le Comité notte avec bcp d’ interet k les projets d’articles [...]
(4) (7) (8)	Réuno in sur . la comptabilite r nationale [...]

5 Domain Adaptation

To adapt our models to the restaurant review domain we apply the following types of techniques: back-translation of in-domain English data, fine-tuning with small amounts of in-domain parallel data, and domain tags.

5.1 Back-translation

Back-translation (BT) is a popular technique for domain adaptation when large amounts of in-domain monolingual data are available (Sennrich et al., 2016b; Edunov et al., 2018). While our in-domain parallel corpus is small (12k pairs), Foursquare contains millions of English-language reviews. Thus, we train an NMT model⁸ in the

⁸Like the “UGC” model with rare character handling and inline case described in Section 6.3.

reverse direction (EN→FR) and translate all the Foursquare English reviews to French.⁹ This gives a large synthetic parallel corpus.

This *in-domain* data is concatenated to the out-of-domain parallel data and used for training.

Edunov et al. (2018) show that doing back-translation with sampling instead of beam search brings large improvements due to increased diversity. Following this work, we test several settings:

Name	Description
BT-B	Back-translation with beam search.
BT-S	Back-translation with sampling.
BT-S × 3	Three different FR samplings for each EN sentence. This brings the size of the back-translated Foursquare closer to the out-of-domain corpus.
BT	No oversampling, but we sample a new version of the corpus for each training epoch.

We use a temperature¹⁰ of $T = \frac{1}{0.9}$ to avoid the extremely noisy output obtained with $T = 1$ and strike a balance between quality and diversity.

5.2 Fine-tuning

When small amounts of in-domain parallel data are available, fine-tuning (FT) is often the preferred solution for domain adaptation (Luong and Manning, 2015; Freitag and Al-Onaizan, 2016). It consists in training a model on out-of-domain data, and then continuing its training for a few epochs on the in-domain data only.

5.3 Corpus tags

Kobus et al. (2017) propose a technique for multi-domain NMT, which consists in inserting a token in each source sequence specifying its domain. The system can learn the particularities of multiple domains (e.g., polysemous words that have a different meaning depending on the domain), which we can control at test time by manually setting the tag. Sennrich et al. (2016a) also use tags to control politeness in the model’s output.

As our corpus (see Section 6.1) is not clearly divided into domains, we apply the same technique as Kobus et al. (2017) but use *corpus* tags (each sub-corpus has its own tag: TED, Paracrawl, etc.) which we add to each source sequence. Like in (Berard et al., 2019), the Foursquare post-edited and back-translated data also get their own tags

⁹This represents ≈15M sentences. This corpus is not available publicly, but the Yelp dataset (<https://www.yelp.com/dataset>) could be used instead.

¹⁰with $p(w_i) = \frac{\exp(z_i/T)}{\sum_{k=1}^{|V|} \exp(z_k/T)}$

Corpus tag	SRC: La carte est trop petite.
TED	The map is too small.
Multi-UN	The card is too small.
PE	The menu is too small.

Figure 1: Example of ambiguous source sentence, where using corpus tags helps the model pick a more adequate translation.

Corpus	Lines	Words (FR)	Words (EN)
WMT	29.47M	1 003M	883.5M
UGC	51.39M	1 125M	1 041M

Table 3: Size of the WMT and UGC training corpora (after filtering).

(PE and BT). Figure 1 gives an example where using the PE corpus tag at test time helps the model pick a more adequate translation.

6 Experiments

6.1 Training data

After some initial work with the WMT 2014 data, we built a new training corpus named UGC (User Generated Content), closer to our domain, by combining: Multi UN, OpenSubtitles, Wikipedia, Books, Tatoeba, TED talks, ParaCrawl¹¹ and Gourmet¹² (See Table 3). UGC does not include Common Crawl (which contains many misaligned sentences and caused hallucinations), but it includes OpenSubtitles (Lison and Tiedemann, 2016) (spoken-language, possibly closer to Foursquare). We observed an improvement of more than 1 BLEU on newstest2014 when switching to UGC, and almost 6 BLEU on Foursquare-valid.

6.2 Pre-processing

We use `langid.py` (Lui and Baldwin, 2012) to filter sentence pairs from UGC. We also remove duplicate sentence pairs, and lines longer than 175 words or with a length ratio greater than 1.5 (see Table 3). Then we apply SentencePiece and our rare character handling strategy (Section 4.1). We use a joined BPE model of size 32k, trained on the concatenation of both sides of the corpus, and set SentencePiece’s vocabulary threshold to 100. Finally, unless stated otherwise, we always use the *inline casing* approach (see Section 4.2).

¹¹Corpora available at <http://opus.nlpl.eu/>

¹²3k translations of dishes and other food terminology <http://www.gourmetpedia.eu/>

6.3 Model and settings

For all experiments, we use the Transformer Big (Vaswani et al., 2017) as implemented in Fairseq, with the hyperparameters of Ott et al. (2018). Training is done on 8 GPUs, with accumulated gradients over 10 batches (Ott et al., 2018), and a max batch size of 3500 tokens per GPU. We train for 20 epochs, while saving a checkpoint every 2500 updates ($\approx \frac{2}{5}$ epoch on UGC) and average the 5 best checkpoints according to their perplexity on a validation set (a held-out subset of UGC).

For fine-tuning, we use a fixed learning rate, and a total batch size of 3500 tokens (training on a single GPU without delayed updates). To avoid overfitting on Foursquare-PE, we do early stopping according to perplexity on Foursquare-valid.¹³ For each fine-tuned model we test all 16 combinations of dropout in $\{0.1, 0.2, 0.3, 0.4\}$ and learning rate in $\{1, 2, 5, 10\} \times 10^{-5}$. We keep the model with the best perplexity on Foursquare-valid.¹⁴

6.4 Evaluation methodology

During our work, we used BLEU (Papineni et al., 2002) on newstest[2012, 2013] to ensure that our models stayed good on a more general domain, and on Foursquare-valid to measure performance on the Foursquare domain.

For sake of brevity, we only give the final BLEU scores on newstest2014 and Foursquare-test. Scores on Foursquare-valid, and MTNT-test (for comparison with Michel and Neubig, 2018; Berard et al., 2019) are given in Appendix. We evaluate “detokenized” MT outputs¹⁵ against raw references using SacreBLEU (Post, 2018).¹⁶

In addition to BLEU, we do an indirect evaluation on an Aspect-Based Sentiment Analysis (ABSA) task, a human evaluation, and a task-related evaluation based on polysemous words.

6.5 BLEU evaluation

Capital letters Table 4 compares the case handling techniques presented in Section 4.2. To better evaluate the robustness of our models to changes of case, we built 3 synthetic test sets from Foursquare-test, with the same target, but all source words in upper, lower or title case.

Model	BLEU	Case insensitive BLEU		
		Upper	Lower	Title
Cased	31.75	16.01	32.39	26.66
LC to cased	30.70	33.03	33.03	33.03
Factored case	31.59	32.25	32.96	29.83
Inline case	31.46	31.08	32.57	29.55
Noised case	31.83	32.61	33.69	33.60

Table 4: Robustness to capital letters (see Section 4.2). Foursquare-test’s source side has been set to upper, lower or title case. The first column is case sensitive BLEU on Foursquare-test. “LC to cased” always gets the same scores because it is invariant to source case.

Model	news	noised news	test
UGC (Inline case)	40.68	35.59	31.46
+ natural noise	40.43	40.35	31.66

Table 5: Baseline model with or without natural noise (see Section 4.3). *Noised news* is the same type of noise, artificially applied to newstest2014.

Inline and factored case perform equally well, significantly better than the default (cased) model, especially on all-uppercase inputs. Lowercasing the source is a good option, but gives a slightly lower score on regular Foursquare-test.¹⁷ Finally, synthetic case noise added to the source gives surprisingly good results. It could also be combined with factored or inline case.

Natural noise Table 5 compares the baseline “inline case” model with the same model augmented with natural noise (Section 4.3). Performance is the same on Foursquare-test, but significantly better on newstest2014 artificially augmented with Foursquare-like noise.

Domain adaptation Table 6 shows the results of the back-translation (BT) techniques. Surprisingly, BT with beam search (BT-B) deteriorates BLEU scores on Foursquare-test, while BT with sampling gives a consistent improvement. BLEU scores on newstest2014 are not significantly impacted, suggesting that BT can be used for domain adaptation without hurting quality on other domains.

Table 7 compares the domain adaptation techniques presented in Section 5. We observe that:

1. Concatenating the small Foursquare-PE corpus to the 50M general domain corpus does not help much, unless using corpus tags.

¹³The best perplexity was achieved after 1 to 3 epochs.

¹⁴The best dropout rate was always 0.1, and the best learning rate was either 2×10^{-5} or 5×10^{-5} .

¹⁵Outputs of our models are provided with the Foursquare corpus.

¹⁶SacreBLEU signature: BLEU+case.mixed+numrefs.1+smooth.exp+tok.13a+version.1.2.10

¹⁷The “LC to cased” and “Noised case” models are not able to preserve capital letters for emphasis (as in Table 2), and the “Cased” model often breaks on such examples.

Model	news	test
UGC (Inline case)	40.68	31.46
UGC \oplus BT-B	40.56	30.14
UGC \oplus BT-S	40.64	32.59
UGC \oplus BT	40.84	32.68
UGC \oplus BT-S \times 3	40.63	32.80

Table 6: Comparison of different back-translation schemes (see Section 5.1). \oplus denotes the concatenation of several training corpora.

Model	Tag	news	test
UGC (Inline case)	–	40.68	31.46
UGC \oplus PE	–	40.80	31.98
UGC + FT	–	39.78	34.97
UGC \oplus PE + tags	–	40.71	32.15
	PE	38.97	34.30
UGC \oplus BT + tags	–	40.67	33.44
	BT	39.02	32.87

Table 7: Domain adaptation with Foursquare-PE fine-tuning (FT) or corpus tags. The “tag” column represents the corpus tag used at test time (if any).

2. *Foursquare-PE + tags* is not as good as fine-tuning with Foursquare-PE. However, fine-tuned models get slightly worse results on news.
3. Back-translation combined with tags gives a large boost.¹⁸ The BT tag should not be used at test time, as it degrades results.
4. Using no tag at test time works fine, even though all training sentences had tags.¹⁹

As shown in Table 8, these techniques can be combined to achieve the best results. The natural noise does not have a significant effect on BLEU scores. Back-translation combined with fine-tuning gives the best performance on Foursquare (+4.5 BLEU vs UGC). However, using tags instead of fine-tuning strikes a better balance between general domain and in-domain performance.

6.6 Targeted evaluation

In this section we propose two metrics that target specific aspects of translation adequacy: translation accuracy of domain-specific polysemous words and Aspect-Based Sentiment Analysis performance on MT outputs.

¹⁸Caswell et al. (2019); Berard et al. (2019) observed the same thing.

¹⁹We tried keeping a small percentage of UGC with no tag, or with an ANY tag, but this made no difference.

Model	news	test
WMT	39.37	26.23
UGC (Inline case)	40.68	31.46
Google Translate (Feb 2019)	36.31	29.63
DeepL (Feb 2019)	?	32.82
UGC \oplus BT + FT	39.55	35.93
UGC \oplus BT \oplus PE + tags	40.99	35.60
Nat noise \oplus BT + FT	39.91	36.25
Nat noise \oplus BT \oplus PE + tags	40.72	35.54

Table 8: Combination of several robustness or domain adaptation techniques. At test time, we don’t use any tag on news, and use the PE tag on Foursquare-test (when applicable). BT: back-translation. PE: Foursquare-PE. FT: fine-tuning with Foursquare-PE. \oplus : concatenation.

French word	Meanings
Cadre	<u>setting</u> , frame, executive
Cuisine	<u>food</u> , kitchen
Carte	<u>menu</u> , <u>card</u> , map

Table 9: French polysemous words found in Foursquare, and translation candidates in English. The most frequent meanings in Foursquare are underlined.

Translation of polysemous words We propose to count polysemous words specific to our domain, similarly to Lala and Specia (2018), to measure the degree of domain adaptation. TER between the translation hypotheses and the post-edited references in Foursquare-PE reveals the most common substitutions (e.g., “card” is often replaced with “menu”, suggesting that “card” is a common mistranslation of the polysemous word “carte”). We filter this list manually to only keep words that are polysemous and that have a high frequency in the test set. Table 9 gives the 3 most frequent ones.²⁰

Table 10 shows the accuracy of our models when translating these words. We see that the domain-adapted model is better at translating domain-specific polysemous words.

Indirect evaluation with sentiment analysis

We also measure adequacy by how well the translation preserves the polarity of the sentence regarding various aspects. To evaluate this, we perform an indirect evaluation on the SemEval 2016 Aspect-Based Sentiment Analysis (ABSA) task (Pontiki et al., 2016). We use our internal ABSA systems trained on English or French SemEval

²⁰Rarer ones are: *adresse* (place, address), *café* (coffee, café), *entrée* (starter, entrance), *formule* (menu, formula), *long* (slow, long), *moyen* (average, medium), *correct* (decent, right), *brasserie* (brasserie, brewery) and *coin* (local, corner).

Model	cadre	cuisine	carte	Total
Total (source)	23	32	29	100%
WMT	13	17	14	52%
UGC (Inline case)	22	27	18	80%
UGC \oplus PE + tags	23	31	29	99%

Table 10: Number of correct translations for difficult polysemous words in Foursquare-test by different models. The first row is the number of source sentences that contain this word. Other domain-adapted models (e.g., “UGC + FT” or “UGC \oplus BT”) also get $\approx 99\%$ accuracy.

ABSA Model	Aspect	Polarity
<i>ABSA French</i>	64.7	83.2
<i>ABSA English</i>	59.5	72.1
<i>ABSA English on MT outputs</i>		
WMT	54.5	66.1
UGC (Inline case)	58.1	70.7
UGC \oplus BT \oplus PE + tags	60.2	72.0
Nat noise \oplus BT \oplus PE + tags	60.8	73.3

Table 11: Indirect evaluation with Aspect-Based Sentiment Analysis (accuracy in %). *ABSA French*: ABSA model trained on French data and applied to the SemEval 2016 French test set; *ABSA English*: trained on English data and applied to human translations of the test set; *ABSA English on MT outputs*: applied to MT outputs instead of human translations.

2016 data. The evaluation is done on the SemEval 2016 French test set: either the original version (ABSA French), or its translation (ABSA English). As shown in Table 11, translations obtained with domain-adapted models lead to significantly better scores on ABSA than the generic models.

6.7 Human Evaluation

We conduct a human evaluation to confirm the observations with BLEU and to overcome some of the limitations of this metric.

We select 4 MT models for evaluation (see Table 12) and show their 4 outputs at once, sentence-by-sentence, to human judges, who are asked to rank them given the French source sentence in context (with the full review). For each pair of models, we count the number of wins, ties and losses, and apply the Wilcoxon signed-rank test.

We took the first 300 test sentences to create 6 tasks of 50 sentences each. Then we asked bilingual colleagues to rank the output of 4 models by their translation quality. They were asked to do one or more of these tasks. The judge did not know about the list of models, nor the model that

Pairs	Win	Tie	Loss
Tags \approx Tags + noise	82	453	63
Tags \gg Baseline	187	337	74
Tags \gg GT	226	302	70
Tags + noise \gg Baseline	178	232	97
Tags + noise \gg GT	218	315	65
Baseline \gg GT	173	302	123

Table 12: In-house human evaluation (“ \gg ” means better with $p \leq 0.05$). The 4 models *Baseline*, *GT*, *Tags* and *Tags + noise* correspond respectively to rows 2 (UGC with inline case), 3 (Google Translate), 6 (Combination of BT, PE and tags) and 8 (Same as 6 with natural noise) in Table 8.

produced any given translation. We got 12 answers. The inter-judge Kappa coefficient ranged from 0.29 to 0.63, with an average of 0.47, which is a good value given the difficulty of the task. Table 12 gives the results of the evaluation, which confirm our observations with BLEU.

We also did a larger-scale monolingual evaluation using Amazon Mechanical Turk (see Appendix), which lead to similar conclusions.

7 Conclusion

We presented a new parallel corpus of user reviews of restaurants, which we think will be valuable to the community. We proposed combinations of multiple techniques for robustness and domain adaptation, which address particular challenges of this new task. We also performed an extensive evaluation to measure the improvements brought by these techniques.

According to BLEU, the best single technique for domain adaptation is fine-tuning. Corpus tags also achieve good results, without degrading performance on a general domain. Back-translation helps, but only with sampling or tags. The robustness techniques (natural noise, factored case, rare character placeholder) do not improve BLEU.

While our models are promising, they still show serious errors when applied to user-generated content: missing negations, hallucinations, unrecognized named entities, insensitivity to context.²¹ This suggests that this task is far from solved.

We hope that this corpus, our natural noise dictionary, model outputs and human rankings will help better understand and address these problems. We also plan to investigate these problems on lower resource languages, where we expect the task to be even harder.

²¹See additional examples in Appendix.

Appendix

Corpus	Emojis	Capitalized	Typos
Foursquare-test	0.17	0.14	3.3
MTNT-test	0.02	0.18	3.8

Table 13: Noise comparison between Foursquare-test and MTNT-test (Michel and Neubig, 2018). Emojis, all-uppercase words (not counting acronyms) and spelling + grammar mistakes (according to MS Word) per 100 tokens.

Model	Foursq. valid	MTNT-test
Berard et al. (2019)		
WMT (Inline case)	–	39.1
+ MTNT domain adaptation	–	44.3
+ Ensemble	–	45.7
Our models (single)		
WMT (Cased)	24.3	39.0
UGC (Cased)	30.4	41.5
UGC (Inline case)	29.3	41.6
UGC \oplus BT + FT	33.7	44.5
UGC \oplus BT \oplus PE + tags	33.7	44.9
Nat noise \oplus BT + FT	33.8	44.6
Nat noise \oplus BT \oplus PE + tags	33.4	44.9

Table 14: Comparison of our models against the winner of the WMT 2019 Robustness Task on the MTNT test set (similar robustness challenges but different domain). We also give cased BLEU of our models on Foursquare-valid. Results on Foursquare-test are shown in the paper.

Large-Scale monolingual evaluation We conducted a larger scale monolingual evaluation using Amazon Mechanical Turk (AMT), as reported in Table 15. We evaluated the translations of 1800 test sentences. To filter poor quality work, which occurs frequently in our experience, we also created gold questions by selecting 40 additional sentences for which we built 3 fake translations each, whose ranking was intentionally unambiguous and easy. We created HITs (Human Intelligence Tasks) of 10 sentences each, of which 3 sentences were gold questions. Workers were also required to have at least 98% task approval rate on AMT and 1000 tasks approved. We aimed for 6 submissions per HIT from 6 different workers. Compared to the in-house evaluation, the inter-judge agreement was low (Kappa of 0.15).

Pairs	Win	Tie	Loss
Tags + noise \gg Tags	1939	7414	1667
Tags + noise \gg Base	2718	6108	2178
Tags + noise \gg GT	3008	5801	2173
Tags \gg Baseline	2657	6110	2225
Tags \gg GT	2950	5794	2234
Baseline \gg GT	2205	6918	1889

Table 15: Large-scale Human Evaluation on Amazon Mechanical Turk (“ \gg ” means $p \leq 0.01$). The 4 models *Baseline*, *GT*, *Tags* and *Tags + noise* correspond respectively to rows 2 (UGC with inline case), 3 (Google Translate), 6 (Combination of BT, PE and tags) and 8 (Same as 6 with natural noise) in Table 8.

Both human evaluations agree and are consistent with the BLEU evaluation, except for the impact of natural noise, where the AMT evaluation found a significant improvement.

Evaluation	# Tasks	# Ties	% Ties	Kappa
In-house	12	3588	57%	0.47
AMT	1321	65988	58%	0.15

Table 16: Size of the human evaluations. AMT: Amazon Mechanical Turk. The AMT kappa (inter-judge agreement) is very low, while the in-house kappa is moderate.

SRC	On s’y sent comme a la maison ! <s> Équipe de serveurs très sympa! <s> Goutez au burger LE Retour d’Hervé , il est a tomber :-)
REF	It feels like home!! <s> Team of waiters very nice! <s> Taste the burger LE Retour d’Hervé, it’s to die for :-)
Type	Bar, Bistro
Location	Paris, FR
Rating	8.29
SRC	Je conseille le crumble fraise/rhubarbe CHAUD . <s> C’est délicieux !!
REF	I recommend the strawberry/rhubard crumble HOT. <s> It’s delicious!!
Type	Bakery, Breakfast Spot
Location	Brussels, BE
Rating	8.88
SRC	Très bons burgers, cheesecake à tomber par terre... <s> Sans oublier <NAME>, <NAME> et <NAME> en un mot CHAR-MANTS!
REF	Very good burgers, cheesecake to die for... <s> Not to mention <NAME>, <NAME> and <NAME>: in a word CHAR-MING!
Type	American Restaurant
Location	Paris, FR
Rating	-

REF	Friendly chip shop stuck to Grand Boulevards. <s> We find the essential Belgian fries. <s> They are DELICIOUSLY big as we like them :) to test. <s> Late opening on the weekend.
Type	Belgian Restaurant, Fast Food Restaurant
Location	Paris, FR
Rating	7.91
SRC	Que de bon souvenir , fillet de boeuf au patte . <s> Merci pour l accueil Mr <NAME>
REF	Great memories, beef fillet with pasta. <s> Thank you for being so welcoming Mr <NAME>
Type	Café, Pizza Place
Location	Libreville, GA
Rating	8.21
SRC	La carte est souvent enrichie. <s> La gérance est top .
REF	The menu is often supplemented. <s> The management is top notch.
Type	Sushi Restaurant
Location	Sid’Bou Said, TN
Rating	7.70

Table 17: Examples of challenging examples from Foursquare-PE. We show the full reviews with sentence delimiters (<s>) and metadata. The words that contain typos or that could cause trouble to a regular NMT model are shown in bold red.

SRC	Le meilleur resto de Belleville, DE LOIN!
REF	The best restaurant in Belleville, BY FAR!
Cased	Best restaurant in Belleville, DE LOIN!
Inline case	The best restaurant in Belleville, BY FAR!
<hr/>	
SRC	ESCALOPE DE VEAU MONTAGNARDE à tomber, et à ne plus pouvoir se lever de sa chaise
REF	ESCALOPE DE VEAU MONTAGNARDE is an absolute knock out and you'll have difficulty recovering
Cased	Falling down and not being able to get up from his chair
Inline case	ESCALOPE OF MOUNTAIN CALF to fall, and not be able to rise from his chair

Table 18: Examples of sentences from Foursquare-test with capitalized words, where default (cased) MT gets the translation wrong and inline case helps.

SRC	Bcp de choix, peut-être Trop :-)
REF	Plenty of choice, maybe too much of it :-)
Inline case	Bcp of choice, maybe Too much :-)
Natural noise	A lot of choices, maybe Too much :-)
<hr/>	
SRC	Service loooooonnnng .
REF	Looooooong wait.
Inline case	Service loooooonnnng .
Natural noise	Long service.

Table 19: Examples of sentences from Foursquare-test with noisy spelling (in bold red), where training with source-side natural noise helps.

SRC	Carte attractive et pas excessive.
REF	Nice menu and not over the top.
Inline case	Attractive and not excessive card .
BT + FT	Attractive menu and not excessive.
<hr/>	
SRC	Cuisine pas originale, service passable, mais l'endroit est joli !
REF	Not very original food , acceptable service, but the place itself is beautiful!
Inline case	Not an original kitchen , fair service, but the place is nice!
BT + FT	Food not original, service passable, but the place is nice!

Table 20: Examples of sentences from Foursquare-test with polysemous words (in bold red), where domain adaptation helps (with Foursquare-PE fine-tuning and back-translation).

SRC	Les frites boff mais leurs burger, une tuerie!	Typo and slang (“bof”)
REF	The fries are meh , but the burgers, to die for!	
MT	The fries are great but their burgers are to die for!	
SRC	Le merveilleux du Merveilleux c’est merveilleux...	“merveilleux” is a pastry, “Merveilleux” is a pastry shop (named entity).
REF	The merveilleux at Merveilleux is marvelous...	
MT	The wonderful of the Wonderful it’s wonderful...	
SRC	La souris d’agneau est délicieuse !	Dish name (translated literally)
REF	The lamb shank is delicious!	
MT	The lamb mouse is delicious!	
SRC	La quantité 5 raviolis qui se battent pour 12.70 euros.	Idiomatic expression (“qui se battent en duel”)
REF	Poor quantity, 5 raviolis or so for 12.70 Euros.	
MT	The quantity 5 dumplings that fight for 12.70 euros.	
SRC	Après le palais du facteur nous voici à la halte qui est un restaurant correct.	Named entities (“Palais Idéal du Facteur Cheval” and “La Halte du Facteur”)
REF	After the Palais du Facteur we stopped at La Halte , which is a reasonable restaurant.	
MT	After the mailman’s palace here we are at the rest stop which is a decent restaurant.	

Table 21: Examples of bad translations by our best model (Noise \oplus BT \oplus PE + tags). All examples are from Foursquare-test, except for the last one, which is from SemEval.
